Alpha-Adrenoreceptor Antagonists and Pial Vessel Diameter During Hypercapnia and Hemorrhagic Hypotension in the Cat

LUDWIG M. AUER, M.D., ULRIKE G. TRUMMER, AND BARBRO B. JOHANSSON, M.D., PH.D.

SUMMARY It has been proposed that sympathetic activation may prevent maximum dilatation of extraparenchymal cerebral vessels during hemorrhagic hypotension and hypercapnia. In the present study, the effect of alpha-adrenoreceptor antagonists (phenoxybenzamine 1.5 mg kg\(^{-1}\) or phentolamine 8 mg kg\(^{-1}\)) on pial vessel diameter was studied in the cat during hypotension and hypercapnia alone or in combination. Two levels of hypercapnia were used (mean Paco\(_2\) 74 and 122 mm Hg respectively). Pial arterial vessels (resting diameter 40–184 \(\mu\)m) were observed by means of a closed cranial window technique using a Leitz intravital microscope, an image splitting eyepiece, and a videoangiometer, the latter giving continuous data on changes of the inspected vessel diameters. Alpha-adrenoreceptor antagonists did not further increase the arterial diameter in any of the situations studied.

Materials and Methods

Seventeen cats were anesthetized with 40 mg kg\(^{-1}\) pentobarbital, immobilized with 60 \(\mu\)g kg\(^{-1}\) pancuroniumbromide, intubated endotracheally and respirated with a 3:1 mixture of \(\text{N}_2\text{O}:\text{O}_2\) using a Loosco respirator (Hoek-Loos, Amsterdam, Holland). Both femoral arteries and one femoral vein were cannulated with Portex catheters for continuous monitoring of blood pressure (Hellige-unit, Hellige, Freiburg, GFR), withdrawal of arterial blood for frequent blood gas controls (AVL gas check type 937C, List, Graz, Austria) and intravenous administration of drugs, respectively.

Pial vessels were observed by means of a closed cranial window technique using a Leitz intravital microscope (Leitz, Wetzlar, GFR), an image splitting eyepiece and a videoangiometer, the latter giving continuous data on changes of the investigated vessels. Alpha-adrenoreceptor antagonists did not further increase the arterial diameter in any of the situations studied.

divided into 4 groups of 6, 5, 3 and 3 cats respectively.

Group 1. PacO₂ was increased from 29 to 117 mm Hg (mean values) by adding CO₂ to the respired gas mixture. CO₂ was withdrawn when maximum hypercapnic vasodilatation had been reached and after normalization of PacO₂. 1.5 mg kg⁻¹ phenoxybenzamine (3 cats) or 8 mg kg⁻¹ phentolamine (3 cats) was injected i.v. Thereafter, hypercapnia was again induced to a mean level of 115 mm Hg.

Group 2. The blood pressure was decreased by withdrawal of arterial blood. Alpha-adrenergic blockade was then induced by i.v. injection of 8 mg kg⁻¹ phentolamine. Continuous observation of arterial diameters as described above was carried out in order to detect any further dilatation.

Group 3. Phentolamine, 8 mg kg⁻¹, was injected i.v. during combined hypotension and hypercapnia (Paco₂ 122 mm Hg). Pial artery changes were simultaneously observed as described above. In these experiments, intracranial pressure (ICP) was monitored by inserting a needle into the cisterna magna to verify the effect of hypercapnia, i.e. the increase of cerebral blood volume and hence ICP.

Group 4. In these cats a moderate degree of hypercapnia was induced (Paco₂ 73.5-75.5 mm Hg) after lowering the blood pressure to 60 mm Hg by bleeding. As soon as a hypercapnic steady state was reached, 1.5 mg kg⁻¹ phenoxybenzamine was injected i.v. and mean arterial pressure (MAP) was kept stable on 60 mm Hg by reinfusion and bleeding.

Statistical differences were evaluated by Student's t-test.

**Results**

Mean arterial pressure, PacO₂, PaO₂, and pial arterial diameter variations during resting conditions and during the experimental procedure are given in table 1.

Group 1. Following the administration of phenoxybenzamine or phentolamine, MAP decreased by 48% and remained low during the second hypercapnic period; arterioles dilated 28.1% to 216.5%. Auto-regulation was observed to be intact in 3 experiments where arterioles constricted with small spontaneous MAP increase. In the other 3 animals, no MAP changes occurred.

The arteriolar reaction to hypercapnia after alpha-receptor blockade was not significantly different from that obtained by hypercapnia alone. Phenoxybenzamine and phentolamine did not differ in this aspect. Figure 1 shows a typical experiment for the group.

Group 2. Bleeding decreased MAP by 41%. During hypotension alone, arterial diameters increased by 3.4% from resting values. Phentolamine did not induce any significant change in diameter (see table 1). Figure 2 shows an individual example from this group.

Group 3. Withdrawal of blood reduced MAP by 49%. MAP increased markedly during hypercapnia and fell sharply after phentolamine was given (see table 1). Pial arterioles dilated by a mean of 25% during hypotension and further dilated 21% during hypercapnia. After injection of phentolamine, there was no increase in arteriolar diameter, but a decrease of 10%. Figure 3 represents an example of this series.

Group 4. Thirteen arterial vessel portions with rest-

FIGURE 1. Experiment from Group 1 showing mean arterial pressure (MAP, broken line, left ordinate) and arterial diameter (ΦA, solid line, right ordinate) during hypercapnia. The left half illustrates the parameters before, the right half after alpha-adreno-receptor blockade with phenoxybenzamine (Ph, 1.5 mg kg⁻¹). H = Hypercapnia.

FIGURE 2. Individual example of Group 2. Following hemorrhagic hypotension, phentolamine (8 mg kg⁻¹) does not induce further arterial dilatation (ΦA). MAP = mean arterial pressure. Further fall in MAP after phentolamine was compensated by reinfusion of blood.

FIGURE 3. Individual cat in group 3. The diameter of 2 pial arterial vessels (ΦA) increases during hemorrhagic hypotension and hypercapnia. Alpha-adrenergic blockade with phentolamine (8 mg kg⁻¹) does not increase the diameter further during this situation. Mean arterial pressure (MAP) increases during hypercapnia and a sharp pressure drop is induced by phentolamine to bring MAP back to the prehypercapnic hypotensive level. Intracranial pressure (ICP) rises as expected during hypercapnia.

Discussion
During sympathetic stimulation phentolamine has been reported to prevent the constriction of pial arteries and to prevent the decrease in cerebral blood flow. There is controversy in the literature regarding the influence of the peripheral sympathetic nerves on

ing diameters of 22–144 μm (mean 86.2 μm) dilated by 13.4% during hypotension and dilated further to 84.9% from resting values by additional hypercapnia. Following intravenous phenoxybenzamine, a slight non-significant further dilatation (mean 2.84 ± 0.6%) was measured. A single example is shown in figure 4.
Figure 4. Single example of hemorrhagic hypotension and hypercapnia in Group 4. PaCO₂ is indicated on the bottom of the figure. Following alpha-adrenergic blockade with intravenous phenoxybenzamine, there is no significant further dilatation in two pial arteries (A), one with a resting diameter of 70 μm, the other with 100 μm.

CO₂-induced cerebrovascular reactivity. This data, indicating an unresponsiveness of pial arterioles to alpha-adrenergic blockade during hypercapnia, is supported by several reports. Stone et al.⁷ and Waltz et al.⁸ observed unchanged CO₂-induced vasodilatation following cervical sympathetic ganglionectomy. Eidelman et al.⁹ reported even a reduced CBF-response following chemical sympathectomy with intracisternal 6-hydroxydopamine. The same group⁹ observed equally decreased CBF-response to hypercapnia following excision of the carotid chemoreceptor bodies, thus excluding the possibility of the CO₂-response being purely chemoreceptor-mediated. James et al.¹⁰ and Kawamura et al.¹¹ found an enhanced increase in blood flow following section of the cervical sympathetic nerve and alpha-receptor blockade, respectively.

The discrepancy between single studies may be derived from different degrees of hypercapnia. As no information is available on the possible influence of the peripheral sympathetic system on different levels of carbon dioxide tension the data are difficult to compare. Different anesthetic agents and levels of anesthesia may also play a role. In the present study 2 levels of PaCO₂ were chosen representing moderate and pronounced hypercapnia (PaCO₂ around 70 and 120 mm Hg, respectively). The fact that alpha-adrenergic blockade was without effect at both levels of hypercapnia is evidence against the possibility that failure to show any adrenergic influence during pronounced hypercapnia was due to a toxic effect on adrenergic receptors.

It is likely that the slight decrease in pial vessel diameter following phentolamine in Group 3 is due to the parallel fall of blood pressure since the phenomenon was missing in the phenoxybenzamine-treated animals in Group 4 where MAP remained constant. Phentolamine passes the blood brain barrier to a lesser extent than phenoxybenzamine which was the reason for using the considerably higher dose of phentolamine. The lack of effect on pial artery diameter in Group 2 and 3 animals where phentolamine was used alone is not likely to be explained by poor drug penetration in light of the results from Group 1 and 4.

The failure to demonstrate any alpha-adrenergic influence on pial arterial tone in our study could be related to the anesthesia used. Although pentobarbital was used to initiate anesthesia the effect of this drug was considered to be low at the time pial arterial diameters were measured when anesthesia was maintained with a mixture of N₂O : O₂. A recent study confirms that pial vessels react to sympathetic activation during conditions corresponding to those in the present study.¹¹ All experiments concerning neurogenic influences on anesthetized animals must be interpreted with some caution. Our results do not support the hypothesis of neurogenically induced vasoconstriction of pial arteries during hypercapnia and/or hemorrhagic hypotension.
