A Systematic Review of Immediate Anticoagulation for Ischemic Stroke of Presumed Cardioembolic Origin

To the Editor:

In the meta-analysis of randomized controlled trials on the efficacy and safety of anticoagulant treatment in acute cardioembolic stroke,1 the timing of anticoagulation in these patients is still a controversial issue. Thus a critical review of all published literature is essential to generate consensus and also as a starting point for further research.

We also performed, presented (ENS Meeting 2006) and published as an abstract2 a systematic review and meta-analysis on this subject that was not mentioned in Paciaroni’s et al review, probably because when our review was presented, his paper was already submitted. Our results also did not support the routine use of anticoagulants in the first 48 hours of an ischemic stroke of presumed cardioembolic origin.

We now update the review including 8 studies: CESG,3 IST,4 Fiss bis,5 TOAST,6 HAEST,7 TAIST,8 Camerlingo et al9 and ARGIS-1 (LaMonte, unpublished data, 2006). The ARGIS-1 study was not included in Paciaroni’s et al review.

Results reveal a significant increase in symptomatic and asymptomatic hemorrhages when comparing anticoagulation with no anticoagulation or aspirin (Figure 1), but favor treatment with anticoagulants for the prevention of recurrent ischemic stroke or stroke of unknown cause (Figure 2).

As we included ARGIS-1 in the review, we could additionally conclude for the lack of evidence in favor of anticoagulants relatively to a favorable outcome at 3 months (Figure 3).

The review of the methodology of individual studies disclosed several important bias and quality limitations. Only one trial9 was specifically designed for cardioembolic strokes. This trial supported acute anticoagulation in nonhypertensive patients, but it was prematurely terminated. All other trials excluded patients with clear indications for anticoagulation. CT scan before treatment was not required for patient inclusion in IST. Low weight was temporarily an exclusion factor in TOAST trial. Advanced age and stroke severity were also exclusion factors in several trials.

Taking into account these methodological limitations, we think that a new pragmatic randomized clinical trial is needed.

Disclosures

None.
