Background and Purpose—Hallmarks of vulnerable atherosclerotic plaques are inflammation that can be assessed with $^{18}$fluorine-fluorodeoxyglucose positron emission tomography/computed tomography, and increased neovascularization that can be evaluated by dynamic contrast–enhanced-MRI. It remains unclear whether these parameters are correlated or represent independent imaging parameters. This study determines whether there is a correlation between inflammation and neovascularization in atherosclerotic carotid plaques.

Methods—A total of 58 patients with transient ischemic attack or minor stroke in the carotid territory and ipsilateral carotid artery stenosis of 30% to 69% were included. All patients underwent positron emission tomography/computed tomography and dynamic contrast–enhanced-MRI of the carotid plaque. $^{18}$Fluorine-fluorodeoxyglucose standard uptake values with target/background ratio were determined. Neovascularization was quantified by the mean (leakage) volume transfer constant $K_{\text{trans}}$. Spearman rank correlation coefficients between target/background ratio and $K_{\text{trans}}$ were calculated.

Results—Images suitable for further analysis were obtained in 49 patients. A weak but significant positive correlation between target/background ratio and mean $K_{\text{trans}}$ (Spearman $\rho=0.30$ [P=0.035]) and 75th percentile $K_{\text{trans}}$ (Spearman $\rho=0.29$ [P=0.041]) was found.

Conclusions—There is a weak but significant positive correlation between inflammation on positron emission tomography/computed tomography and neovascularization as assessed with dynamic contrast–enhanced-MRI. Future studies should investigate which imaging modality has the highest predictive value for recurrent stroke, as these are not interchangeable.

Key Words: atherosclerosis ◼ imaging ◼ inflammation ◼ magnetic resonance imaging ◼ neovascularization ◼ plaque, atherosclerotic ◼ positron-emission tomography ◼ vascular diseases

Stroke is the fourth leading cause of death in the United States and a leading cause of long-term disability. Atherosclerosis is underlying in the majority of clinical cardiovascular events, such as stroke. Inflammation is an important feature of plaque progression and vulnerability. It can be quantified noninvasively with $^{18}$fluorine-fluorodeoxyglucose ($^{18}$F-FDG) positron emission tomography/computed tomography (PET-CT) with excellent reproducibility.

Neovascularization is another important feature of vulnerable atherosclerotic plaques. Dynamic contrast–enhanced MRI (DCE-MRI) enables quantitative assessment of neovascularization in carotid atherosclerotic plaques. $K_{\text{trans}}$ is a parameter that reflects microvascular flow, permeability, and surface area. The aim of the present study was to investigate the relation between inflammation and neovascularization as assessed with PET-CT and DCE-MRI, respectively. In a secondary analysis, we investigated the relation between these parameters and plaque morphology itself as determined with MRI. In addition, the relation between clinical characteristics, $K_{\text{trans}}$ and $^{18}$F-FDG uptake were evaluated.
Methods

Patients

Patients with recent (<3 months) amaurosis fugax, transient ischemic attack or minor stroke in the carotid territory and ipsilateral carotid plaque causing a mild to moderate (30%–69%) stenosis at Doppler ultrasonography, were eligible for inclusion. Cardiovascular risk factors and the use of medication were assessed by a questionnaire. The study was approved by the institutional Medical Ethical Committee. All patients gave written informed consent.

Imaging

PET-CT examination and the multisequence MRI have in detail been described previously. Parameters of the DCE-MRI protocol have been published as well.

Image Analysis

The analysis of the PET-CT images was performed using a dedicated workstation. To determine the target/background ratio (TBR), the standard uptake values were normalized to blood 18F-FDG activity by dividing them by the mean standard uptake value of blood as measured in the internal jugular vein (Figure). TBR is considered to be a reflection of arterial FDG uptake and reflective of underlying macrophage activity.

Plaque morphology was manually assessed using dedicated vessel wall analysis software (VesselMASS; LUMC, The Netherlands). The operator was blinded for the PET-CT results. Quantification of neovascularization was done using a custom-made Matlab program (Matlab version 7.5; The Mathworks, Natick, MA), using the Patlak model and a generalized vascular input function. The mean $K^{trans}$ per patient was determined. In addition, histogram analysis was performed to determine the 75th percentile $K^{trans}$, which is more reflective for hot spots with high $K^{trans}$ values (Figure).

Statistical Analysis

To correlate TBR with $K^{trans}$, Spearman rank correlation coefficient was calculated using SPSS version 20 (SPSS Inc, Chicago, IL). Relation between clinical characteristics, TBR and $K^{trans}$, was explored by univariate linear regression analysis. A P value of <0.05 was considered statistically significant.

Results

In total 58 patients were included. Nine of them had to be excluded, because of poor DCE-MRI quality. Patients underwent PET-CT 36.7±19.4 days and DCE-MRI 33.7±19.6 days after their last neurological symptoms. Mean time interval between both examinations was 2.9±5.5 days.

For the 49 patients analyzed, clinical characteristics and their relation between $K^{trans}$ and 18F-FDG are displayed in Table 1.

The mean TBR was calculated as 1.45±0.26. The morphological parameters of the plaque as determined with MRI are given in Table 2. The mean and 75th percentile $K^{trans}$ were determined as 0.11±0.03 and 0.15±0.04 min⁻¹, respectively. A positive weak correlation between TBR and $K^{trans}$ was found

Cl indicates confidence interval; and TBR, target/background ratio.
(mean $K_{\text{trans}}$, Spearman $\rho$ of 0.30 [$P=0.035$]; 75th percentile $K_{\text{trans}}$, Spearman $\rho$ of 0.29 [$P=0.041$]). No significant correlations between TBR and $K_{\text{trans}}$ in relation to the morphological parameters were observed.

### Discussion

The purpose of this study was to investigate the relation between inflammation (PET-CT) and neovascularization (DCE-MRI) in carotid atherosclerotic plaques. We demonstrated that higher FDG uptake is weakly associated with increased microvasculature within the plaque. Cyran et al.\(^1\) also showed positive correlation between the mean TBR and the extraction fraction of DCE-MRI. Both imaging modalities provide information about hallmarks of plaque vulnerability, but it is unknown whether these imaging features are interchangeable or provide additive information. This study proves that, in symptomatic patients with mild to moderate (30%–69%) stenosis, PET-CT and DCE-MRI features of the plaque are related with each other, although the information provided is not interchangeable. This is expressed in the relative low correlation coefficient ($\rho$ of 0.30; $P<0.05$). However, we have not studied the use of these techniques for treatment decision making. Further studies should determine the clinical usage of inflammation and neovascularization for the individual patient’s management.

### Conclusions

There is a weak but significant positive correlation between inflammation on PET-CT and neovascularization as assessed with DCE-MRI. Future studies should investigate that which imaging modality has the highest predictive value for recurrent stroke, as these are not interchangeable.

### Acknowledgments

We thank B.J. Meems, MD, A.H.C.M.L. Schreuder, MD and N.P. van Orshoven, MD, PhD for their contribution in patient inclusion, F.M. Mottaghy, MD, PhD, S. Vöö, MD, and M.E. Gaens, MSc for their substantive contribution and R.J. van der Geest, MSc, MD for providing us the software (VesselMass) to analyze the data.

### Sources of Funding

This research was performed within the framework of the Center for Translational Molecular Medicine (www.ctmm.nl), project PARISK (Plaque At RISK; grant 01C-202), and supported by the Dutch Heart Foundation.

### Disclosures

None.
